

Decision tree: Working with a categorical raster

What do you want from the classes?

to read
what they are

is.factor() cats() freq()

is.factor() reports whether a layer is categorical, cats() returns the table pairing each code with its label, and freq() counts the cells in each class

to draw them

geom_spatraster() scale_fill_coltab()

the color table in the file is used when there is one; scale_fill_coltab() applies another raster's table, and a raster with none takes a discrete fill scale

to build them
from a quantity

classify(m) then levels(x) <-

m is a matrix of lower bound, upper bound and new value; an unmatched cell keeps its own value unless others is set, and the result holds codes, not classes

to merge them

classify(lookup) then levels(x) <-

lookup pairs each old code with a new one; classify() reads the codes and ignores the labels, so the new table attaches to the codes the merge produced
