

Decision tree: Choosing a map algebra operation

What is the calculation?

from one cell

LOCAL

arithmetic ifel() classify()

arithmetic keeps the name of its first operand; classify() takes a matrix of lower bound, upper bound and new value; NA in either input returns NA

from a neighborhood around each cell

FOCAL

focal()

w is an odd number of cells, not a distance; fun takes a name or a function of your own; the mean of a zero-one layer is the proportion of the window

from every cell of a class

ZONAL

zonal()

summarizes one raster within the classes of another, and the two have to share a grid

from the whole layer

GLOBAL

global()

returns one row per layer rather than a raster
