

Workflow: Reading a raster

`rast("file.tif")`

reads the header rather than the values, so `inMemory()` is `FALSE` until something asks for them

then

**`nrow()` `ncol()` `ncell()` `nlyr()`
`res()` `ext()` `crs()` `global()`**

the pieces of the printed summary one at a time, and `global()` the values; `res()` is in the units of the CRS

then

`geom_spatraster(aes(fill = layer))`

maps the first layer to fill unless one is named, and resamples to maxcell cells before drawing; `scale_fill_hypso_c()` and its family color a quantity

then

`select()` `rename()` `mutate()` `filter()`

act on layers rather than columns; `filter()` sets the failing cells to NA and removes nothing, and `as_tibble()` is the last resort that leaves the grid
