

Workflow: The parts of a Shiny app

AT THE TOP OF THE FILE

attach the packages; read, project and resample

this runs once when the app starts, so everything that does not depend on an input belongs here

then

THE USER INTERFACE

fluidPage() sliderInput() plotOutput()

an input carries an inputId naming the value it produces; an output placeholder names where a result will be drawn

then

THE SERVER

function(input, output, session)

reactive() holds a calculation that depends on an input and is re-evaluated only when that input changes; renderPlot() and renderText() assign to output\$<id>

then

shinyApp(ui, server)

joins the two halves and runs them; nothing passes between them except through input and output, so a name that differs is why an app runs and shows nothing
