

Decision tree: Working with points

What do you need from your points?

records that
are not repeats

distinct()

the geometry is a column, so it takes part unless `st_drop_geometry()` removes it first

one feature
per group

summarize()

unions each group into a `MULTIPOINT`, holding each position once

one row per point
from a multipoint

st_cast("POINT")

one row per point, with the fields copied onto every one of them

one point to stand
for a polygon

st_point_on_surface()

a point inside the polygon; `st_centroid()` can fall outside a long or curved one

points across
a study area

st_sample()

size is exact for random sampling and approximate for regular and hexagonal
