

Workflow: Reducing what a script costs

MEASURE

obj_size() bench::mark() profvis()

the size of an object, its geometry and its fields; the time of alternatives; the slow line of a whole script

then

READ LESS

st_write() to a GeoPackage, then query = and wkt_filter =

the fields, rows and area the question needs, read before the data reach R; on a text file a query parses everything

then

KEEP LESS

select() st_drop_geometry() st_simplify() aggregate()

drop the fields and the geometry a question does not use; simplify or aggregate a copy for drawing

then

SAVE WHAT WAS BUILT

write_rds() then read_rds()

run the pre-processing once and read its result

then

LET TERRA MANAGE THE VALUES

inMemory() sources() mem_info() writeRaster()

rast() reads the header; a result stays in memory when it fits and goes to a temporary file when it does not
