

Workflow: Measuring spatial autocorrelation

NEIGHBORS

`st_contiguity()` `st_knn()` `st_dist_band()`

polygons that touch, the k nearest points, or the points within a range of distances; state the choice

then

WEIGHTS

`st_weights()`

each neighbor an equal share of one, by default

then

THE GLOBAL STATISTIC

`global_moran()` `global_moran_perm()` `autocor()`

Moran's I, tested by shuffling the values; `autocor()` does all three steps for a raster, whose neighbors are the grid

then

WHERE THE CLUSTERS ARE

`local_moran()` `%>% unnest()`

one statistic and one label per polygon; keep the labels with small p-values and read the blocks, not the singles

and

HOW FAR IT REACHES

`st_dist_band()` `inside map2_dbl()`

Moran's I for each band of distance; the distance at which it reaches zero is the range, and samples closer than that are not independent
