

Workflow: Version control with git and GitHub

SET UP ONCE

use_git_config() git_default_branch_configure() git_vaccinate()

the name and email on every commit, main as the branch,
RStudio's files ignored everywhere; git_sitrep() checks it

then

MAKE THE PROJECT A REPOSITORY

use_git_ignore() then use_git()

decide what is not tracked before the first commit,
because a committed file stays in the history

then

CONNECT TO GITHUB ONCE

create_github_token() gitcreds_set() use_github()

the token is stored where R can find it and a script
cannot; use_github() creates the remote and pushes

then

THE CYCLE

edit > stage > commit > push

one change per commit, with a message that says
what the change was for

then

WORK WITH OTHERS

pull before starting, commit before pulling

create_from_github() starts a project from a repository
that exists; use_readme_md() says how to run it
